Consider *M* regression models $y_m(\mathbf{x}), 1 \le m \le M$ predicting $h(\mathbf{x})$. Each individual prediction error is

$$\epsilon_m(\mathbf{x}) = h(\mathbf{x}) - y_m(\mathbf{x}) \; ,$$

with an averaging committee:

$$y(\mathbf{x}) = \frac{1}{M} \sum_{m=1}^{M} y_m(\mathbf{x})$$

(日)、

э

$$E_{COM} = \frac{1}{M^2} \mathbb{E}_{\mathbf{x}} \left[\sum_{m=1}^{M} \epsilon_m^2(\mathbf{x}) + 2 \sum_{m \neq n} \epsilon_m(\mathbf{x}) \epsilon_n(\mathbf{x}) \right] = \frac{1}{M} E_{AV}$$

Introduction	Bagging and Boosting		
Combining models			Slide 7/37
Why com	mittees?		Ň

In theory, committees can vastly reduce the expected error of individual classifiers

- Make the expected error arbitrarily small by increasing M
- In practice, the classifiers are highly correlated
 - The error reduction is then small
- But: it can be shown that

$$E_{AV} \ge E_{COM}$$

• We can improve the performance of committees by decreasing the correlation between the classifiers

JNIVERSITY OF AMSTERDAM

Consider multiple training data sets $D = \{(\mathbf{x}_n, t_n)\}$ of fixed size Taking the expected squared loss of a model, we can decompose:

$$\mathbb{E}_{D}[(y_{D}(\mathbf{x}) - t)^{2}] = \underbrace{(\mathbb{E}_{D}[y_{D}(\mathbf{x})] - t)^{2}}_{\text{bias}^{2}} + \underbrace{\mathbb{E}_{D}[(y_{D}(\mathbf{x}) - \mathbb{E}_{D}[y_{D}(\mathbf{x})])^{2}]}_{\text{variance}}$$

Interpretation:

- The bias captures how well the model *can* perform. Flexible models will have low bias.
- The variance captures how much the end model depends on the specific dataset. Flexible models will have high variance.

JNIVERSITY OF AMSTERDAM

Consider multiple training data sets $D = \{(\mathbf{x}_n, t_n)\}$ of fixed size Taking the expected squared loss of a model, we can decompose:

$$\mathbb{E}_{D}[(y_{D}(\mathbf{x}) - t)^{2}] = \underbrace{(\mathbb{E}_{D}[y_{D}(\mathbf{x})] - t)^{2}}_{\text{bias}^{2}} + \underbrace{\mathbb{E}_{D}[(y_{D}(\mathbf{x}) - \mathbb{E}_{D}[y_{D}(\mathbf{x})])^{2}]}_{\text{variance}}$$

Interpretation:

- The bias captures how well the model *can* perform. Flexible models will have low bias.
- The variance captures how much the end model depends on the specific dataset. Flexible models will have high variance.

Bias-Variance decomposition

Bias-Variance decomposition:

- Gives us insight into how a particular model generalises
 - High bias-low variance models do not learn from the data
 - Low bias-high variance models overfit on the training data
 - Optimal model flexibility (e.g., regularisation): good bias-variance trade-off.
- Has little practical value: single training dataset
- Provides insight into why committees are useful

Optimal ensemble learning

For best ensemble performance, we want the base learners to be as accurate as possible and as diverse as possible

Bagging			Slide 13/37

Bagging: Bootstrap Aggregation

We rarely have infinite training datasets...

- Nor do we have many
- Using bootstrapping, we can create new datasets
- The correlation between datasets is then known and kept small
- Bootstrap aggregation:

Simply average the outcomes of classifiers trained on different bootstrap datasets

Bagging

- Improves results with high-variance models
- No independent datasets (\Rightarrow small improvements)
- Cannot help with high bias models

[Shapire 1990]: Weak learners in the same class as strong learners

Boosting

A technique to combine weak learners to form a strong learner

Adaptive boosting:

- Assign each training datapoint a weight
- Iterate:
 - Train a classifier based on the weighted training data
 - Assign this classifier a weight based on how well it performs
 - Update the datapoints' weights based on how many classifiers classify it correctly

Adaboost can be interpreted as minimising

$$E = \sum_{n=1}^{N} \exp\left(-\frac{t_n}{2} \sum_{m=1}^{M} \alpha_m y_m(\mathbf{x}_n)\right)$$

As a consequence:

- It strongly penalises misclassifications, not robust to outliers!
- It does not generalise to more than 2 classes
- Octoosing a different error function
 - Allows multiclass classification and even regression (e.g. Gradient Boosting)
 - Makes robust classifiers possible

Tree-based models split the input space in regions

- Each region gets its own classifier
- The classifiers can be extremely simple (typically: constant)

Intelligent Autonomous Systems

	Bagging and Boosting	Tree-based models 000●00	
Classification trees			Slide 28/37
Tree-bas	ed models		Ř
			C

- Interpretable!
- Simple and fast
- If let to grow, will learn perfect classification on the training data

Pros

 Pruning (using validation set) allows proper generalisation • Final tree depends strongly on particular data

Cons

- Hard decisions, aligned with dimensions
- Finding best tree is intractable

NIVERSITY OF AMSTERDAM

	Bagging and Boosting	Tree-based models ○○○○●○	
Random Forests			Slide 29/37
Random	Forests		Š

Combine trees with bagging and random feature selection Procedure: for N datapoints and M features, pre-specify $m \ll M$

- Repeat K times:
 - Get a bootstrap sample
 - At each node in the tree:
 - select *m* features at random
 - Pind the optimal split based on these m features and the training set
 - S Fully grow the tree (no pruning)

This is often considered one of the most powerful committee methods

 Slide 34/37

Hierarchical Conditional Mixture Models

The distribution specified by each mixture element can be anything

• Including a Conditional Mixture Model

$$p(\mathbf{x}) = \sum_{k=1}^{K} \pi_k(\mathbf{x}) p(\mathbf{x}|k)$$

- If π were a constant, this would simplify to a normal mixture model (with ∑_k L_k elements)
- Since π(x) can be a complex function of x, the HCM can model very complex distributions
- Notice the similarity with MDN!

Hierarchical Conditional Mixture Models

The distribution specified by each mixture element can be anything

• Including a Conditional Mixture Model

$$p(\mathbf{x}) = \sum_{k=1}^{K} \pi_k(\mathbf{x}) \sum_{l=1}^{L_k} \pi_{kl}(\mathbf{x}) p(\mathbf{x}|l)$$

- If π were a constant, this would simplify to a normal mixture model (with ∑_k L_k elements)
- Since π(x) can be a complex function of x, the HCM can model very complex distributions
- Notice the similarity with MDN!

	Bagging and Boosting		Summary
			Slide 37/37
Wrap-up			Ŵ

To summarise:

- Combine models to improve their expressive power (cfr. Mixture of Gaussians)
- Combining independent models can dramatically improve performance
- Making different models responsible for different areas of the space combines simple models into very flexible models

Exercise session:

- Questions
- Mock exam

Lab session:

• No additional lab exercise, so you can prepare for the exam.
